Abstract

Traditionally metronidazole is used in the treatment of bacterial vaginosis, trichomoniasis, amoebiasis and is also used in combination with other drugs to treat *Helicobacter pylori* (*H. pylori*) that causes stomach or intestinal ulcers. The main aim of this study was to develop a gastroretentive floating pellets for the treatment of above pathological conditions. Such kind of dosage form may provide an extension of drug presence in the upper GI tract resulting enhanced absorption and improved bioavailability for the treatment against protozoa and bacteria. Nine formulations of metronidazole floating pellets such as F1, F2, F3, F4, F5, F6, F7, F8 and F9 were prepared by ionic gelation method using different quantities of sodium alginate and psyllium husk. The drug and polymer ratio were 1:1.4, 1:1.5, 1:1.6, 1:1.6, 1:1.7, 1:1.8, 1:1.8, 1:1.9 and 1:2.0, respectively. The *in vitro* drug release study was carried out in 900 ml phosphate buffer (pH 7.4) at $37\pm 0.5^\circ\text{C}$ and 50 rpm for 12 hours using USP XXIV paddle method and the content of drug release was determined by UV spectrometer at 277nm. Maximum and minimum drug release were found in F1 (88.63%) and in F6 (73.21%), respectively. It indicates that increase in sodium alginate concentration decreases drug release. All the formulations were buoyant for more than 12 hours in simulated gastric fluid at 37°C . The maximum and minimum bulk density tapped were 0.57 and 0.52 in F1 and F9, respectively where drug loading were 14.07% in F1 and 12.56% in F9 which indicates that bulk density of the pellets is directly proportional to drug loading. The maximum and minimum swelling were in F3 (75%) and F7 (59%), respectively which demonstrate that swelling of pellets were inversely proportional to the sodium alginate concentration but it is directly proportional to psyllium husk content. In addition, the psyllium husk keeps the GI tract healthy by scavenging toxins and residues of digestive systems. Therefore, it can be concluded that combination of sodium alginate and biodegradable psyllium husk can be prospectively used for the preparation of gastroretentive floating pellets.

Key words: Gastric retension, floating pellet, ionotropic gelatination technique, metronidazole

Introduction

The design of oral control drug delivery systems (DDS) is primarily aimed to achieve more predictable and increased bioavailability. Now-a-days most of the pharmaceutical scientists are involved in developing the ideal DDS, which should have advantage of single dose for the whole duration of treatment and it should deliver the active drug directly at the specific site. Scientists have succeeded to develop a system and it encourages the scientists to develop control release systems. Control release implies the predictability and reproducibility to control the drug release, drug concentration in target tissue and optimization of the therapeutic effect of a drug by modifying its release in the body with lower and less frequent doses.

Under certain circumstances prolonging the gastric retention of a delivery system is desirable for achieving greater therapeutic benefit of the drug substances. For example, drugs that are absorbed in the proximal part of the gastrointestinal tract and the drugs that are less soluble or are degraded by the alkaline pH may benefit from the prolonged gastric retention. In addition, for local and sustained drug delivery to the stomach and the proximal small intestine to treat certain conditions, prolonging gastric retention of the therapeutic moiety may offer numerous advantages including improved bioavailability, therapeutic efficacy and possible reduction of the dose size. The main principle of GRDDS is to prolong the release of drug at the site of absorption and one of the most recent approaches for the prolongation of gastric retention time is the floating drug delivery systems. Due to

low bulk density of the floating dosages form, they can float in the gastric environment for longer period of time which attributes to improve bioavailability of the drug (Nayak *et al.*, 2010).

It is known that gastroretention time of a drug is affected by several factors, but the gastric emptying time in human is particularly influenced by the size of the orally administered object. Therefore, various approaches for prolonging drug gastroretention have been investigated and floating system has been found to be promising as it prolongs the gastroretention without influencing the size of the orally administered dosage form. Thus, metronidazole will be very effective for the treatment of *H. pylori* infection. At the same time it will be very much effective in the treatment of other antibacterial and antiprotozoal diseases. Hence, the present study was designed to develop floating pellets of metronidazole using sodium alginate and biodegradable natural polymer psyllium husk (Biswas *et al.*, 2012)

Materials and Methods

Metronidazole was obtained as a gift sample from Globe Pharmaceuticals Ltd., Noakhali. Sodium alginate and calcium chloride were purchased from Loba Chemie, India. Psyllium husk was procured from Sajib limited, Bangladesh. All other chemicals used were of analytical grade.

Method of preparation of Pellets: Pellets were prepared by ionotropic gelatination technique. To prepare metronidazole floating pellets sodium alginate and psyllium husk were accurately weighed and dissolved in small amount of distilled water and soaked for overnight. Then psyllium husk was filtered and added to sodium alginate. The mixture was homogenized using propeller stirrer (2775 rpm) for 30 minutes. Metronidazole (500 mg) and distilled water were added to make final volume up to 35 ml., and was homogenized thoroughly using propeller stirrer for 30 minutes to form smooth viscous dispersion. Then liquid paraffin was added to the above viscous dispersion and homogenized for 15 minutes using propeller stirrer and then sprayed on to cationic solution (CaCl₂, 4%) using a syringe having diameter 21G from a height of 4 cm. Sprayed droplets were retained for 2-3 minutes to complete curing reaction. The Pellets were collected by decantation and washed repeatedly by

distilled water, dried at room temperature for 12 hours (Biswas *et al.*, 2012)

Particle size analysis: The diameter of beads was determined by using micrometer. For this purpose, 10 dried pellets were randomly selected from each batch and diameter was measured from three different angles of each pellets. The mean diameters were calculated using following formula. Mean particle size = \sum (mean particle size of the fraction \times weight fraction) / \sum (weight fraction) (Chourasia *et al.*, 2004). Color and shape of dried beads of each batch were observed under trinocular microscope and light microscope.

Surface morphology: The surfaces and cross-section morphologies of the pellets were observed with a scanning electron microscope (SEM) (JSM-6490 LA, JEOL, Tokyo, Japan) operated at an acceleration voltage of 25 kV. The pellets were made conductive by sputtering thin coat of platinum under vacuum using Jeol JFC-1600 autofine coater and then the images were recorded at different magnifications.

Determination of drug content and entrapment efficiency: The pellets (100mg) were weighed and crushed in a mortar and pestle and the crushed material was dissolved in 10 ml of phosphate buffer. The mixture was shaken for about 15 minutes. The solution was then made up to 100ml with phosphate buffer. From this solution 1 ml was taken into 100ml volumetric flask and 99ml of phosphate buffer (pH7.4) was added for dilution. Metronidazole content was estimated by UV-spectrophotometer at 277 nm. The drug content and entrapment efficiency were determined by the following equations (Nappinnai *et al.*, 2007).

$$\% \text{ Drug content} = \{ \text{Weight of drug present in pellets (gm)} / \text{Weight of quantity of pellets (gm)} \} \times 100$$

$$\% \text{ Entrapment efficiency} = (\text{Experimental drug content} / \text{Theoretical drug content}) \times 100$$

FTIR studies: The infrared (IR) spectra were recorded using an FTIR spectrophotometer (Shimadzu FTIR 8400S, Japan) by the KBr pellet method between 4000 and 400 cm⁻¹. The spectra obtained for metronidazole and physical mixtures of metronidazole with polymers were compared to check compatibility of drug with polymers.

In vitro buoyancy study: The time between the introduction of the pellets into the medium and its

Table 2. Physical properties and percentage yield of metronidazole pellets.

Formulation	% Yield	Bulk density (gm/ml)		Mean Diameter ± RSD	Shape of beads
		Untapped	Tapped		
F1	83	0.56	0.57	1.027 ± 0.0381	Spherical
F2	92	0.55	0.54	1.026 ± 0.0734	Spherical
F3	92	0.54	0.55	1.024 ± 0.0231	Spherical
F4	92	0.52	0.54	1.022 ± 0.0557	Spherical
F5	88	0.51	0.52	1.026 ± 0.0312	Spherical
F6	96	0.52	0.53	1.023 ± 0.0921	Spherical
F7	82	0.51	0.52	1.022 ± 0.0545	Spherical
F8	88	0.52	0.53	1.023 ± 0.0154	Spherical
F9	87	0.50	0.52	1.021 ± 0.0732	Spherical

Surface morphology: SEM was used to observe the surface morphology of gastroretentive floating pellets of metronidazole. It was observed that the surface was rough (Figure 2) and further magnification (Figures 3 and 4) some particles were found. It indicates that the drug was successfully incorporated in the pellets.

Swelling index of metronidazole floating pellets: The pellets were significantly swelled in phosphate buffer having pH 7.4, than any other media. The swelling indices of pellets were inversely proportional to the sodium alginate content, but directly proportional to psyllium husk content (Table 5, Figure 9)

In vitro drug release study: The *in vitro* drug release study was carried out in 900 ml phosphate buffer (pH 7.4) at 37±0.5°C and 50 rpm for 12 hours using USP XXIV paddle method and the content of drug release was determined by UV spectrometer at 277 nm. Drug release

were found in F1 (88.63%), F2 (82.62%) and F3 (79.84%). It indicates that increase in sodium alginate concentration decreases drug release (Figure10). Drug release were found in F4 (79.39%), F5 (77.25%) and F6 (73.21%). It indicates that increase in sodium alginate concentration decreases drug release (Figure11). Drug release were found in F7 (84.27%), F8 (82.22%) and F9 (81.81%). It indicates that increase in sodium alginate concentration decreases drug release (Figure 12).

Formulation	Zero-order r^2	First-order r^2	Higuchi-matrix r^2	Korsmeyer-Peppas r^2	Hixson-Crowell r^2	Best Fitted
F1	0.973	0.925	0.958	0.952	0.960	Zero- order
F2	0.927	0.991	0.992	0.975	0.981	Higuchi-matrix
F3	0.926	0.975	0.989	0.980	0.972	Higuchi-matrix
F4	0.965	0.960	0.963	0.947	0.974	Hixon-Crowell
F5	0.969	0.969	0.970	0.965	0.980	Hixon-Crowell
F6	0.950	0.980	0.988	0.984	0.979	Higuchi-matrix
F7	0.940	0.990	0.991	0.980	0.987	Higuchi-matrix
F8	0.928	0.993	0.995	0.981	0.985	Higuchi-matrix
F9	0.929	0.909	0.991	0.931	0.929	Higuchi-matrix

In vitro dissolution kinetics of metronidazole floating pellets: To analyze mechanism of drug release and release rate kinetics from the metronidazole floating pellets, the data obtained were fitted in zero-order release, first-order kinetic, Higuchi-matrix, Korsmeyer-Peppas and Hixson-Crowell equation (Table 6).

Formulations F1, F2 and F3 containing drug- polymer ratio of 1:1.41, 1:1.51, 1:1.61 and percent drug release after 12 hours were 88.63, 82.62 and 79.84%, respectively. Formulations F4, F5 and F6 containing drug-polymer ratio of 1:1.61, 1:1.71, 1:1.81 and percent drug release after 12 hours were 79.39, 77.25 and 73.21%, respectively. Formulations F7, F8 and F9 containing drug-polymer ratio 1:1.81, 1:1.91, 1:2.0 and percent drug release after 12 hours were 84.27, 82.22 and 81.81%, respectively.

It is quite evident from the above that the drug release decreases as the amount of sodium alginate increases. In this model curve most of formulations are best fitted to Higuchi-matrix model.

Conclusions

In the present study metronidazole gastroretentive floating pellets were successfully prepared using sodium alginate and psyllium husk to increase gastric retention time and subsequently to retard drug release. From the above experiment we can conclude that:

- Psyllium husk and sodium alginate can be used as combination polymer to make gastroretentive floating pellets
- Sodium alginate decreases the drug release with the increase in its concentration.
- Bulk density of the pellets is directly proportional to drug loading.
- Sodium alginate decreases the swelling of pellets with the increase in its concentration but psyllium husk increases the swelling of pellets with the increase in its concentration.

- In addition to the above psyllium husk is a natural biodegradable polymer which helps to keep the GI tract healthy by soaking up toxins and harmful residues of digestive systems.
- Further study on formulation optimization, stability and in-vivo study will confirm the appropriateness of these formulated gastroretentive metronidazole floating pellets.
